

PRINT()

01. Simple Print

`print()` is a function to take in values and print them. It just print the message verbatim onto the screen.

```
print("Parotta Salna")
```

02. fstrings

```
name = "Parotta Salna"  
print(f"Welcome to {name}")
```

fstrings allow you to embed expressions inside string literals, using curly braces {}.

03. Separator

sep stands for separator and is assigned a single space (' ') by default.

```
print("python", "separator")  
# python separator  
  
print("python", "separator", sep="+")  
# python+separator
```

04. format

```
name = "john"  
age = "23"  
print("My name is {} and I am {} years old.".format(name, age))  
# My name is john and I am 23 years old.  
  
print("My name is {1} and I am {0} years old.".format(age, name))  
# My name is john and I am 23 years old.  
  
print("The capital of {country} is {capital}.".format(country="France", capital="Paris"))  
# The capital of France is Paris
```

05. Concatenate

Concatenate two or more strings with +

```
temperature = 22.5  
print("The temperature is " + str(temperature) + " degrees Celsius.")
```
